

# TACO LOOP

## A Decision Architecture for Unknown Data, Environmental Factors, and Correct Action Under Uncertainty

### White Paper v1.0

Prepared for classHuman - Lawrence Jefferson II / Menoko OG Original Geek and Luxgirl

#### Core Product Law

Unknown data must increase decision discipline, not model confidence.

*Scope: TACO Loop only. This paper intentionally excludes adjacent project architectures and treats TACO as the root system.*

# 1. Executive Summary

**The TACO Loop is a decision-control architecture for unknown-data environments.** It is designed for conditions where available data is incomplete, contradictory, stale, adversarial, environmentally distorted, or falsely treated as certain. TACO forces the system to take in unknowns, assess them against memory and environmental context, choose bounded action under uncertainty, operate with traceability, observe outcomes, and update future decision behavior.

## Definition

TACO = Take In Unknowns -> Assess and Align -> Choose Correctly -> Operate and Observe Outcome.

| Stage   | Function                                                                                 | Operational Test                                      |
|---------|------------------------------------------------------------------------------------------|-------------------------------------------------------|
| Take In | Capture unknown data, weak signals, anomalies, environmental inputs, and declared goals. | Did the system state what it knows and does not know? |
| Assess  | Fuse unknowns with memory, rules, environmental factors, and uncertainty classes.        | Did the system slow down when evidence was weak?      |
| Choose  | Select the best justified action under risk, uncertainty, and guardrails.                | Was the decision bounded, reversible, and traceable?  |
| Operate | Execute or recommend action, observe outcome, audit the decision, and update memory.     | Did outcome evidence feed the next loop?              |

**Commercial positioning:** TACO is not another agent. It is a control layer for agents, humans, workflows, and operational systems that must make proper decisions when they do not yet know enough.

# 2. Problem Statement

Most AI and human workflow systems behave as if the available input is sufficient to decide. Real environments do not work that way. Operational decisions often start with incomplete data, conflicting signals, stale records, tool uncertainty, time pressure, adversarial manipulation, resource limits, and shifting environmental conditions.

The failure path is:

unknown data + environmental pressure + fast action = bad decision probability increase

The corrected path is:

unknown data  
-> structured observation  
-> memory/context recall  
-> environmental assessment  
-> uncertainty classification  
-> guarded choice

- > controlled action
- > outcome observation
- > memory update

### Operational thesis

A decision is not proper just because it produces an answer. A decision is proper when it is made from bounded uncertainty, environmental awareness, rule compliance, and observable outcome feedback.

## 3. TACO Definition

TACO is defined as a four-stage loop: Take In, Assess, Choose, Operate. It is intentionally simple at the command level and rigorous underneath at the model level.

| TACO Element            | Meaning                                                                                               | Failure Prevented                             |
|-------------------------|-------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| T - Take In Unknowns    | Identify knowns, missing facts, contradictions, assumptions, stale data, and environmental variables. | False certainty and hidden assumptions.       |
| A - Assess and Align    | Align observations with memory, context, rules, risk state, and environmental field conditions.       | Context loss and environment-blind decisions. |
| C - Choose Correctly    | Score candidate actions by utility, risk, uncertainty, reversibility, and rule compliance.            | Premature or high-blast-radius action.        |
| O - Operate and Observe | Execute or recommend bounded action, capture outcome, audit trace, and update future patterns.        | Unlearned failure and untraceable decisions.  |

## 4. Source-Validated Foundations

TACO is original architecture, not a copy of one existing framework. Its validation base comes from established decision, control, uncertainty, governance, and observability literature.

| TACO Claim                                                                                                                                 | Source Foundation                                      | Citation |
|--------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|----------|
| A decision loop can be structured around observation, orientation, decision, and action.                                                   | OODA loop decision-cycle lineage.                      | [1]      |

## 5. Mathematical Model

### 5.1 Unknown-Data State

Let the true world state be  $W_t$ . TACO assumes the system does not directly see  $W_t$ . It sees an observation  $Z_t$  that may be distorted by environmental factors and noise.

$$Z_t = O(W_t, E_t, N_t)$$

Core rule:  $Z_t \neq W_t$

| Symbol | Meaning                                                |
|--------|--------------------------------------------------------|
| $W_t$  | True world state.                                      |
| $Z_t$  | Observed data or signal packet.                        |
| $O$    | Observation function.                                  |
| $E_t$  | Environmental factors.                                 |
| $N_t$  | Noise, distortion, missing data, or sensor/tool error. |

#### Design implication

The system must not treat observation as truth. It must model the gap between what is seen and what is real.

### 5.2 Environmental Factor Model

$E_t = \{\text{time\_pressure, volatility, resource\_constraint, system\_load, adversarial\_pressure, tool\_state, external\_conditions}\}$

$D_{\text{env}}(t) = f(\text{volatility, ambiguity, interference, time\_pressure, resource\_constraint})$

$Q_{\text{obs}}(t) = \text{completeness}(Z_t) * \text{accuracy}(Z_t) * \text{freshness}(Z_t) * \text{environmental\_fit}(Z_t, E_t)$

if  $Q_{\text{obs}}(t) < \theta_{\text{obs}}$ :

slow\_loop

gather\_more\_context

restrict\_action\_scope

### 5.3 Uncertainty Classification Model

| Class       | Meaning                     | TACO Response                   |
|-------------|-----------------------------|---------------------------------|
| Known known | Verified data is available. | Proceed within normal controls. |

|                         |                                                  |                                                     |
|-------------------------|--------------------------------------------------|-----------------------------------------------------|
| Known unknown           | Missing fact is identified.                      | Request, retrieve, estimate, or bound.              |
| Unknown unknown         | Relevant missing factor is not yet identified.   | Broaden observation and slow the loop.              |
| Aleatoric uncertainty   | Inherent randomness or environmental volatility. | Hedge, risk-bound, and prepare fallback.            |
| Epistemic uncertainty   | Knowledge gap or model ignorance.                | Gather data, validate, or escalate.                 |
| Adversarial uncertainty | Data or instructions may be manipulated.         | Verify provenance and distrust single-source input. |

$U_t = \{U_{\text{missing}}, U_{\text{aleatoric}}, U_{\text{epistemic}}, U_{\text{adversarial}}, U_{\text{environmental}}, U_{\text{tool}}\}$

$U_{\text{total}}(t) = w_1 * U_{\text{missing}} + w_2 * U_{\text{aleatoric}} + w_3 * U_{\text{epistemic}} + w_4 * U_{\text{adversarial}} + w_5 * U_{\text{environmental}} + w_6 * U_{\text{tool}}$

if  $U_{\text{total}}(t)$  rises:

decision\_speed decreases

verification\_requirement increases

action\_scope decreases

## 5.4 Memory and Recall Model

In TACO, memory is not a chat transcript. It is decision memory: past cases, environmental patterns, validated outcomes, rules, audit trails, and repeated failure signatures.

$M_t = \{M_{\text{working}}, M_{\text{case}}, M_{\text{pattern}}, M_{\text{rule}}, M_{\text{outcome}}, M_{\text{audit}}, M_{\text{subliminal}}\}$

$\text{Recall}_i = \text{similarity}(Z_t, M_i) * \text{trust}(M_i) * \text{relevance}(M_i) * \text{freshness}(M_i) * \text{environmental\_match}(M_i, E_t) * \text{permission\_scope}(M_i)$

## 5.5 Assess and Choose Models

$C_t = \text{Assess}(Z_t, E_t, M_t, U_t, G_t)$

$Q_{\text{assess}}(t) = \text{coherence}(C_t) * \text{memory\_support}(C_t) * \text{environmental\_fit}(C_t) * \text{uncertainty\_resolution}(C_t) * \text{rule\_alignment}(C_t)$

$a_t^* = \text{argmax}_a U(a \mid C_t, U_t, E_t, G_t)$

$U(a) = \text{Benefit}(a) - \text{Cost}(a) - \text{Risk}(a) - \text{UncertaintyPenalty}(a) - \text{RuleViolationPenalty}(a)$

## 5.6 Risk and Guardrail Models

$\text{Risk}(a) = \text{Impact}(a) * P_{\text{failure}}(a) * \text{Exposure}(a) * \text{Irreversibility}(a) * U_{\text{total}}(t)$

$G(a) = P_{\text{rule}}(a) * P_{\text{permission}}(a) * P_{\text{scope}}(a) * P_{\text{safety}}(a) * P_{\text{reversibility}}(a)$

if any guardrail factor == 0:

block\_or\_escalate\_action

| Risk Class | Range       | TACO Behavior                      |
|------------|-------------|------------------------------------|
| Low        | 0.00 - 0.25 | Proceed with audit.                |
| Medium     | 0.26 - 0.50 | Proceed with validation and trace. |
| High       | 0.51 - 0.75 | Human review required.             |
| Critical   | 0.76 - 1.00 | Stop unless explicitly authorized. |

## 5.7 Subliminal Long-Term Loop

The subliminal loop is a background pattern-consolidation layer. It does not claim biological subconsciousness. It means repeated exposure, outcome evidence, and corrected decisions adjust future recall weighting and future uncertainty sensitivity.

$$B_{\{t+1\}} = B_t + \alpha * Lessons_t + \beta * Repetition_t + \gamma * FailurePattern_t + \kappa * CorrectOutcome_t - \delta * Noise_t$$

$$Recall_{i\_prime} = Recall_i + \lambda * B_i$$

## 5.8 TACO Master Equation

$$Decision_t = Operate(Choose(Assess(TakeIn(U_t, E_t, Z_t), Recall(M_t, Z_t, E_t), Align(G_t, C_t))))$$

$$S_{\{t+1\}} = Update(S_t, Decision_t, Outcome_t, Validation_t, B_t)$$

$$B_{\{t+1\}} = \Phi(B_t, Outcome_t, Lessons_t, FailurePattern_t, CorrectDecision_t)$$

# 6. Operational Architecture

  - > [Guardrail + Risk Gate]
  - > [Action / Recommendation Layer]
  - > [Outcome Observation]
  - > [Audit + Learning Layer]
  - > [Subliminal Long-Term Pattern Layer]

| Layer                   | Primary Responsibility                                                                 | Evidence Produced                        |
|-------------------------|----------------------------------------------------------------------------------------|------------------------------------------|
| Ingress API             | Receive requests, files, events, and actor context.                                    | Request ID, input hash, actor ID.        |
| Unknown Data Engine     | Detect knowns, missing data, contradictions, assumptions, stale items.                 | UnknownDataProfile.                      |
| Environment Engine      | Model time, volatility, pressure, adversarial conditions, tool state.                  | EnvironmentState.                        |
| Uncertainty Classifier  | Score missing, epistemic, aleatoric, adversarial, environmental, and tool uncertainty. | UncertaintyProfile.                      |
| Assessment Engine       | Fuse context and determine whether the system knows enough to decide.                  | AssessmentContext.                       |
| Decision Control Engine | Generate and score candidate actions.                                                  | Decision candidates and selected action. |
| Guardrail + Risk Gate   | Block, restrict, or escalate invalid actions.                                          | GuardrailResult.                         |
| Audit + Learning Layer  | Record trace and update decision                                                       | Hash-chained audit record.               |

|  |         |  |
|--|---------|--|
|  | memory. |  |
|--|---------|--|

## 7. Decision Validity and Risk Control

ValidDecision(a\_t) = Observed(a\_t) AND Contextualized(a\_t) AND EnvironmentallyFit(a\_t) AND  
UncertaintyBounded(a\_t) AND RuleCompliant(a\_t) AND OutcomeObservable(a\_t)

| Validity Gate       | Question                                                       | Fail Behavior                     |
|---------------------|----------------------------------------------------------------|-----------------------------------|
| Observed            | Was the input captured and traceable?                          | Request capture or reject action. |
| Contextualized      | Was the scenario aligned to memory, rules, and domain context? | Slow loop and assess again.       |
| Environmentally fit | Was the action adapted to external conditions?                 | Restrict action.                  |
| Uncertainty bounded | Was uncertainty scored and bounded?                            | Escalate or gather more data.     |
| Rule compliant      | Did permissions, scope, safety, and reversibility pass?        | Block action.                     |
| Outcome observable  | Can the result be measured and fed back?                       | Do not commit high-impact action. |

## 8. TACO-UDD Benchmark

TACO requires rigorous proof. The proposed benchmark is TACO-UDD: Unknown-Data Decision Benchmark. It compares baseline model behavior against TACO-controlled behavior under the same unknown-data scenario.

| Metric | Meaning                     | Why It Matters                                                          |
|--------|-----------------------------|-------------------------------------------------------------------------|
| UDS    | Unknown Detection Score     | Did the system detect missing, stale, conflicting, or unsupported data? |
| EFS    | Environmental Fit Score     | Did the decision adapt to external conditions?                          |
| DRS    | Decision Restraint Score    | Did the system avoid premature or excessive action?                     |
| GCS    | Guardrail Compliance Score  | Did action stay within rules, permission, and scope?                    |
| AES    | Action Escalation Score     | Did high-risk uncertainty route to human review?                        |
| DTS    | Decision Traceability Score | Can the decision path be reconstructed?                                 |
| ORS    | Outcome Recovery Score      | Did the system correct course after feedback?                           |

$TACO\_Score = 0.20*UDS + 0.15*EFS + 0.20*DRS + 0.15*GCS + 0.10*AES + 0.10*DTS + 0.10*ORS$

### Primary MVP claim to prove

TACO reduces premature or unsafe decisions under unknown-data conditions while preserving useful action.

## 9. Implementation Stack

| Layer           | Recommended MVP Choice             | Reason                                                   |
|-----------------|------------------------------------|----------------------------------------------------------|
| Backend         | FastAPI / Python                   | Clear control-plane logic and strong schema validation.  |
| Database        | PostgreSQL                         | Reliable source of truth and relational audit structure. |
| Vector recall   | pgvector first                     | Avoids extra infrastructure early.                       |
| Cache/session   | Redis                              | Fast working memory and queue backing.                   |
| Background jobs | Celery + Redis                     | Supports subliminal consolidation jobs.                  |
| Frontend        | React + Vite                       | Fast web control dashboard.                              |
| Mobile          | React Native + Expo                | Shared TypeScript logic and rapid mobile deployment.     |
| UI              | Tailwind + shadcn/ui               | Clean tactical panels.                                   |
| Observability   | OpenTelemetry + structured logs    | Decision trace and runtime visibility.                   |
| Deployment      | Railway backend / Netlify frontend | Fast MVP hosting.                                        |

## 10. Mobile and Role-Based Control Panels

TACO becomes operational when each role has the correct command surface. The platform should support mobile-first control panels with role and subscription boundaries.

| Role       | Primary Panel Mission                                           | Critical Controls                             |
|------------|-----------------------------------------------------------------|-----------------------------------------------|
| Customer   | Submit scenarios and review decision reports.                   | Scenario runner, results, history, export.    |
| Operator   | Monitor active decisions and approve bounded actions.           | Escalation queue, approve/deny, request data. |
| Admin      | Manage users, policies, thresholds, billing, and subscriptions. | RBAC, policy packs, org settings.             |
| Engineer   | Inspect traces, failures, scores, and runtime diagnostics.      | Trace viewer, replay, logs, model cost.       |
| Programmer | Build plugins, tools, rules, and workflow extensions.           | Tool registry, SDK docs, sandbox.             |

|                |                                                                     |                                                  |
|----------------|---------------------------------------------------------------------|--------------------------------------------------|
| Security       | Monitor adversarial flags, permission denials, and audit anomalies. | Alerts, sessions, tool locks, incident mode.     |
| QRF / Reviewer | Fast human intervention for high-risk decisions.                    | Critical packet, approve, deny, pause, redirect. |

### Mobile design rule

Unknowns must be visible. Risk must be impossible to miss. Action buttons must show reversibility. Audit must be one tap away.

## 11. Non-Claims and Boundaries

| Statement                                                  | Position                                                           |
|------------------------------------------------------------|--------------------------------------------------------------------|
| TACO eliminates uncertainty.                               | No. TACO bounds and manages uncertainty.                           |
| TACO proves perfect decisions.                             | No. TACO improves decision discipline and traceability.            |
| TACO replaces OODA.                                        | No. TACO extends the loop logic for unknown-data environments.     |
| TACO is only for AI.                                       | No. It applies to human, AI, and human-agentic decision workflows. |
| TACO's subliminal loop is biological subconsciousness.     | No. It is an architecture for background pattern weighting.        |
| TACO should permit high-impact autonomous actions in v0.1. | No. MVP blocks irreversible actions and escalates high risk.       |

## 12. Conclusion

**TACO is a decision-control system, not a slogan.** Its purpose is to force discipline into the moment where bad systems usually fail: the gap between incomplete evidence and premature action. By treating unknown data, environmental factors, uncertainty classes, guardrails, auditability, and outcome feedback as first-class variables, TACO creates a path toward safer, more accountable decisions in frontier-agentic and human-operational environments.

### Final definition

The TACO Loop is a decision-control architecture for unknown-data environments. It slows premature action, structures uncertainty, incorporates environmental factors, retrieves relevant memory, applies rules and risk boundaries, selects the best justified action, observes the outcome, and consolidates lessons into future decision behavior.
